quants

Programmable fee routing for token launches, built on Meteora DBC.

Every launch is a yield stream. We decide, per token, where its trading fees flow: to stakers, to a basket of real assets, to liquidity, or to the agents that manage it.

LIVE ON MAINNET SINCE OCTOBER 3

$164K
traded

534
unique traders

2,296
trades across 8 tokens

405
on-chain payouts by our keeper

Figures from the quants production database, October 13, 2026.

THE PROBLEM

Launchpads earn fees on every trade, and almost none of it reaches the people who hold.

Fee splits are hard coded per platform. There is no way for a token to say where its own fees go, so every launch becomes a short trade instead of an asset worth holding.

OUR THESIS

A token's trading fees are a cash flow. DBC makes that cash flow programmable.

Configurable curve

Shape, quote token and graduation set per launch, not per platform.

Claimable fees

Partner and creator fees can be claimed and routed by our own logic.

Owned liquidity

Migration into DAMM v2 leaves a locked position that keeps earning.

HOW IT WORKS

Trading fees pay the stakers

01

Launch

Pick a name, a pair token, a trading fee and a reward basket of up to ten verified tokens.

02

Trade

Every trade pays a fee. Most of it is swapped into the reward basket.

03

Stake

Stakers get the basket streamed to them. Longer locks earn more.

THE DBC LIFECYCLE IN QUANTS

Every stage of the curve is a decision we make per token

Stage	What quants does with it
Config	A DBC config per launch profile: curve shape, quote token, fee tier and graduation threshold chosen from the creator's intent
Quote token	Pairs beyond SOL: our own token, stablecoins, and next tokenized stocks, so each curve fills in the asset it belongs to
Fees	A keeper claims DBC fees every few minutes and routes them by policy: creator, stakers' basket, liquidity or treasury
Graduation	Migration into DAMM v2 with the LP position locked for good and owned by the protocol, so liquidity never leaves
After	The locked position's fees keep flowing into the same routing, so a token keeps paying holders long after the curve ends

ENGINEERING

Built to move money safely

An idempotent ledger

Every split and payout is a keyed step, so nothing is ever paid twice, even after a crash.

Books checked first

The keeper checks the ledger against wallet balances and stops before moving anything if they disagree.

RPC failover

Reads and sends switch between Infura, Helius and Alchemy when one goes down.

ROADMAP 1 · STOCKS AND REAL WORLD ASSETS

Launches priced in equities, yield paid in real assets

Stock paired curves

DBC curves quoted in tokenized stocks (xStocks, Backpack Onchain, Ondo), with curve shapes tuned for lower volatility pairs.

RFQ first buys

A creator's first buy fills the stock quote through an RFQ desk, so launching on an equity pair costs one signature.

Treasury bill baskets

Route the stakers' share into tokenized treasuries, so meme volume pays holders a real world yield.

Community equity clubs

A token whose fees buy a basket of stocks the community picks and votes on, held for every staker.

ROADMAP 2 · FEE POLICY AS CODE

Curves and fee schedules people can publish and reuse

Config preset marketplace

Curators publish DBC configs (fair launch, long curve, anti sniper) and earn a share of fees from every launch that uses them.

Decaying launch fees

High fees in the first minutes that fall on a schedule, so snipers fund the stakers instead of draining them.

Conviction gated graduation

Graduation that also needs a share of supply staked and locked, so tokens reach DAMM v2 with holders, not only volume.

Fee routing API

Any app can launch through quants with its own routing rules and get a live stream of fee flows by webhook.

ROADMAP 3 · AGENTS AND COMPOUNDING LIQUIDITY

The full Meteora stack, run by agents

Compounding liquidity

Fees from the locked DAMM v2 position are added back to it, so a token's liquidity deepens every day it trades.

DLMM after graduation

Part of the treasury runs concentrated DLMM ranges around the price, so mature tokens get tighter spreads.

Agent managed baskets

An AI agent rebalances a token's reward basket within limits its holders vote on, and reports every move.

Agents that launch

Agents launch and run their own tokens through our routing, with fees funding the agent's treasury and its stakers.

WHY THIS MATTERS FOR METEORA

More assets on one liquidity layer, and launches worth holding.

quants turns DBC from a launch tool into the start of a token's whole life: priced in any asset, paying its holders, and graduating into liquidity that stays and grows.
